1

A UI/UX design for an e-commerce app focuses on making the system simple, clear, and easy to use. The home screen should display popular products, categories, and a search bar so users can quickly find what they need. Navigation should be straightforward, with clear icons and menus that guide users through the app. Product pages must show images, prices, and short descriptions. The checkout process should be quick and simple, with fewer steps to reduce confusion. UX design also ensures the app loads fast and works smoothly on different devices. Feedback like loading signs and confirmation messages helps users understand actions. A good design improves user experience, increases customer satisfaction, and helps the business grow.

2

User-centered design is a design method that focuses on the needs of users. It starts by understanding users through research such as interviews, surveys, and observations. Designers then create solutions based on what users need and expect. Testing is also important, where users try the system and give feedback. The design is improved based on this feedback. This process makes sure the final product is easy to use and meets user expectations. User-centered design helps reduce errors, improve usability, and increase user satisfaction.

3

Figma is a popular tool used to create UI prototypes for web and mobile applications. In Figma, designers can create screens, add buttons, text, and images, and connect them to show how the app works. This allows developers and designers to see the flow of the app before building it. It also supports teamwork because multiple people can work on the same design. Using Figma helps reduce mistakes because problems can be found early. It also saves time and improves communication. Overall, Figma is useful for designing and testing ideas before development starts.

4

A mobile UI/UX architecture shows how different parts of an app are connected. It includes screens like the home page, product page, cart, and checkout. Each screen is linked in a simple way so users can move easily through the app. Navigation should be clear to avoid confusion. The architecture helps developers understand how to build the app step by step. The purpose is to create a smooth and simple experience for users. It improves usability, reduces errors, and ensures users can complete tasks easily.
